

## Graphs (cont.)

- Different types of graphs:
  - Directed vs. undirected edges
  - Presence or absence of cycles

## Graph Representations

- Graph  $G = (V, E)$ 
  - $V$  represents the set of vertices (nodes).
  - $E$  represents the set of edges (links).
  - Both vertices and edges may contain additional information.
- E.g.
  - $V = \{1, 2, 3, 4, 5\}$
  - $E = \{(1, 2), (1, 5), (2, 5), (2, 4), (4, 5), (2, 3), (2, 4)\}$
- Standard ways to represent a graph
  - Vertices and edges:  $G = (V, E)$ : Not good for computational purposes

	$n_1$	$n_2$	$n_3$	$n_4$	$n_5$
$n_1$	0	1	0	0	0
$n_2$	0	0	1	0	1
$n_3$	0	0	0	1	0
$n_4$	0	0	0	0	1
$n_5$	1	1	1	0	0

adjacency matrix

$n_1$  [ $n_2, n_4$ ]  
 $n_2$  [ $n_2, n_4$ ]  
 $n_3$  [ $n_2, n_4$ ]  
 $n_4$  [ $n_2, n_4$ ]  
 $n_5$  [ $n_1, n_2, n_3$ ]

adjacency lists

## Adjacency Matrices

- Represent a graph as an  $n \times n$  square matrix  $M$ .
  - $n = |V|$
  - $M_{ij} = 1$  means a link from node  $i$  to  $j$
- Advantages:
  - Naturally encapsulates iteration over nodes.
  - Rows and columns correspond to inlinks and outlinks.
- Disadvantages:
  - Lots of zeros for sparse matrices
  - Lots of wasted space
- Standard ways to represent a graph
  - Vertices and edges:  $G = (V, E)$ : not good for computational purposes

	1	2	3	4
1	0	1	0	1
2	1	0	1	1
3	1	0	0	0
4	1	0	1	0

## Adjacency Lists

- An array  $Adj$  of  $|V|$  lists.
- For each  $u$  in  $V$ , the adjacency list  $Adj[u]$  contains all the vertices  $v$  such that  $(u,v)$  in  $E$ .
- Take adjacency matrices...and throw away all the zeros.

## Adjacency List Is Preferred

- Adjacency list is usually preferred, because it provides a compact way to represent **sparse** graphs: those for which  $|E|$  is much less than  $|V|$ .
- Adjacency matrix may be preferred when the graph is **dense**, or when we need to be able to tell quickly if there is an edge connecting two given vertices.
- Adjacency list is preferred in the following:
  - In a social network of  $n$  individuals, there are  $n(n - 1)$  possible friendships (where  $n$  may be on the order of billions). However, even the most gregarious will have relatively few friends compared to the size of the network (thousands, perhaps, but still far smaller than hundreds of millions).
  - The same is true for the hyperlink structure of the web: Each individual web page links to a minuscule portion of all the pages on the web.

## Paths and Graph Traversals

- In graph theory, a path in a graph is a finite or infinite sequence of edges that connect a sequence of vertices, which, by most definitions, are all distinct from one another.
- Directed path:
  - In a directed graph, a directed path (sometimes called dipath) is again a sequence of edges (or arcs) that connect a sequence of vertices but with the added restriction that the edges all be directed in the same direction.

## Directed Graph

Undirected

Directed

## Graph Traversal: A Path as an Alternating Sequence of Vertices and Edges

Source	Destination	Distance	Shortest Paths
JFK	LAX	3	JFK-ORD-PHX-LAX
LAS	MCO	4	LAS-PHX-DFW-HOU-MCO and four others
HOU	JFK	2	HOU-ATL-JFK and two others

A path/walk of length  $k$  in a graph is an alternating sequence of vertices and edges,  $v_0, e_0, v_1, e_1, v_2, \dots, v_{k-1}, e_{k-1}, v_k$ , which begins and ends with vertices.

## Graph Properties

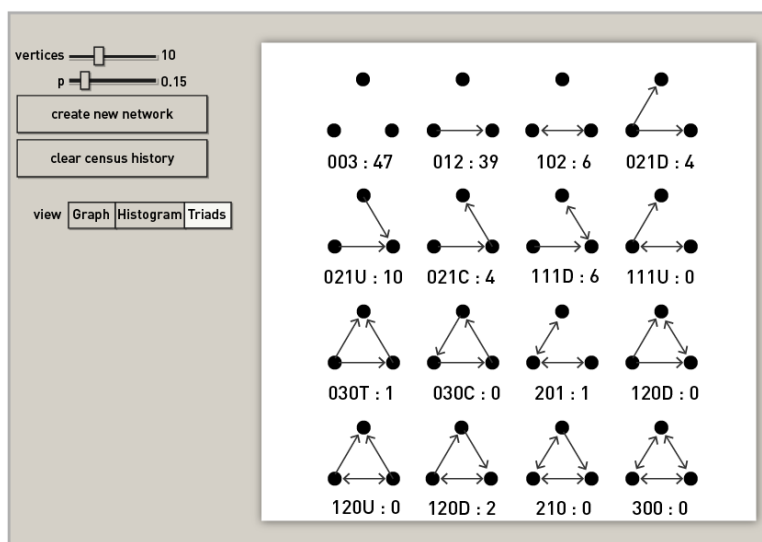

An example graph, with the properties of being **planar** and being **connected**, and with order 6, size 7, **diameter** 3, **girth** 3, **vertex connectivity** 1, and **degree sequence**  $\langle 3, 3, 3, 2, 2, 1 \rangle$ .

## Connected Component

A connected component (or just component) of an undirected graph is a subgraph in which any two vertices are connected to each other by paths, and which is connected to no additional vertices in the supergraph.

## Study Graphs Using Triads
